Resumen

AlphaDeepChess: motor de ajedrez basado en podas alpha-beta

Los motores de ajedrez han influido notablemente en el desarrollo de estrategias computacionales y algoritmos de juego desde mediados del siglo XX. Informáticos de la talla de Alan Turing y Claude Shannon sentaron las bases para el desarrollo de este campo. Posteriormente, las mejoras de hardware y software y la evolución de la heurística se asentarían sobre estos cimientos, incluida la introducción de la poda alfa-beta, una optimización del algoritmo minimax que reducía significativamente el número de nodos evaluados en un árbol de juego. Con el aumento de la potencia de cálculo, motores modernos como Stockfish o Komodo aprovechan no sólo las optimizaciones de búsqueda, sino también los avances en heurística y, en algunos casos, la inteligencia artificial mediante redes neuronales.

Abstract

AlphaDeepChess: chess engine based on alpha-beta pruning

Chess engines have significantly influenced the development of computational strategies and game-playing algorithms since the mid-20th century. Computer scientists as renowned as Alan Turing and Claude Shannon set the foundations for the development of the field. Thereafter, hardware and software improvements and the evolution of heuristics would build upon these foundations, including the introduction of alpha-beta pruning, an optimization of the minimax algorithm that significantly reduced the number of nodes evaluated in a game tree. With increasing computational power, modern engines such as Stockfish or Komodo leverage not only search optimizations but also advancements in heuristics and, in some cases, artificial intelligence using neuronal networks.

Chapter 1

Introduction

“The most powerful weapon in chess is to have the next move”

— David Bronstein

Chess, one of the oldest and most strategic games in human history, has long been a domain for both intellectual competition and computational research. The pursuit of creating a machine that could compete with the best human players, chess Grandmasters (GM), was present. It was only a matter of time before computation surpassed human computational capabilities.

In 1997, the chess engine Deep Blue made history by defeating the world champion at the time, Garry Kasparov, marking the first time a computer had defeated a reigning world champion in a six-game match under standard chess tournament time controls¹.

Since then, the development of chess engines has advanced rapidly, moving from rule-based systems to AI-driven models. However, classical search algorithms, such as alpha-beta pruning, continue to be fundamental to understanding the basics of efficient search and evaluation of game trees.

1.1. Objectives

- Develop a functional chess engine using alpha-beta pruning as the core search algorithm.
- Optimize search efficiency by implementing move ordering, quiescence search, and iterative deepening to improve pruning effectiveness.
- Implement transposition tables using Zobrist hashing to store and retrieve previously evaluated board positions efficiently.
- Implement multithreading to enable parallel search.
- Ensure modularity and efficiency so that the engine can be tested, improved, and integrated into chess-playing applications.

¹[https://en.wikipedia.org/wiki/Deep_Blue_\(chess_computer\)](https://en.wikipedia.org/wiki/Deep_Blue_(chess_computer))

- Profile the engine to identify performance bottlenecks and optimize critical sections of the code.
- Compare performance metrics against other classical engines to evaluate the impact of implemented optimizations.

1.2. Work plan

1. Research phase and basic implementation: understand the fundamentals of alpha-beta pruning with minimax and position evaluation. Familiarize with the UCI (Universal Chess Interface) and implement the move generator with its specific exceptions and rules.
2. Optimization: implement quiescence search and iterative deepening to improve pruning effectiveness.
3. Optimization: improve search efficiency using transposition tables and Zobrist hashing.
4. Optimization: implement multithreading to enable parallel search.
5. Profiling: use a profiler to identify performance bottlenecks and optimize critical sections of the code.
6. Comparison: use Stockfish to compare efficiency generating tournaments between chess engines.
7. Analyze the results and write the final report.

Chapter 2

State of the art

2.1. Board representation

Let's introduce the battlefield where the game takes place: the chessboard, which serves as the foundation for all operations.

In order to store a position setting with its pieces and its piece colors and other additional information like the side to move¹, the castling rights² or the fifty-move rule counter³, we can encounter different types of representations: piece centric, square centric and hybrid solutions. We chose to use bitboards as the primary representation, complemented by a piece list to store the piece on each square (piece centric representation). Additionally, the game state is stored in a bit field.

A **bitboard**⁴, also known as a bitset or bitmap, is a 64-bit word structure that efficiently represents a chessboard because it matches with the number of squares: every bit corresponds to a square of the chessboard.

A **bit field**, in contrast to a bitboard, uses a fixed number of bits within an integer to store multiple small values or flags.

For example, using a 64-bit bitfield, we can allocate 6 bits to store the number of pieces on the board, as $2^6 = 64$ possibilities. This means the bits would occupy an interval from X included to $X + 5$.

For more information about board representation, refer to the Wikipedia page: https://www.chessprogramming.org/Board_Representation

¹Corresponds to the colour that has the turn of movement.

²Refers to the possibilities for each side to castle both short and long. Castling is explained in 3.2.5.1.

³This rule is explained in 4.

⁴https://www.chessprogramming.org/Board_Representation

2.2. Game trees

Sequential games, such as chess or tic-tac-toe, where players take turns alternately, unlike simultaneous games, can be represented in a game tree or graph. In this representation, each node is a possible option or game state, and child nodes branch out to represent subsequent states, forming a tree-like structure. This tree has a height or depth that refers to the number of levels or layers in the tree, starting from the root node (the initial game state) and extending to the leaf nodes.

The depth of a chess game tree is important because it determines the extent to which it will be analysed and evaluated. A depth of 1 represents all possible moves for the current player or side to move, while a depth of 2 includes the opponent's responses to those moves. As the depth increases, the tree grows exponentially, making it computationally expensive to explore all possible states.

The search algorithms in these game trees will be discussed below.

Chapter 3

Work description

3.1. Where to begin?

Let's start from the beginning. What is chess? Chess is a board game where two players who take white pieces and black pieces respectively compete to first checkmate¹ the opponent.

What about a chess engine? A chess engine consists of a software program that analyzes chess positions and returns optimal moves depending on its configuration. In order to help users to use these engines, chess community agreed on creating an open communication protocol called **Universal Chess Interface** or commonly referred to as UCI, that provides the interaction with chess engines through user interfaces.

In the following section 3.2, we will talk about the basic concepts of chess, but if you already have the knowledge we recommend you to advance directly to the section 3.3.

3.2. Basic concepts

Chess is a game of strategy that takes place on a chessboard with specific rules governing the movement and interaction of the pieces. This section introduces the fundamental concepts necessary to understand how chess is played.

3.2.1. Chessboard

A chessboard is a game board of 64 squares, 8 rows by 8 columns. To refer to each of the squares we mostly use **algebraic notation**² using the numbers from 1 to 8 and the letters from "a" to "h". There are also other notations like descriptive notation³ which is obsolete or ICCF numeric notation⁴ due to chess pieces have

¹<https://en.wikipedia.org/wiki/Checkmate>

²[https://en.wikipedia.org/wiki/Algebraic_notation_\(chess\)](https://en.wikipedia.org/wiki/Algebraic_notation_(chess))

³https://en.wikipedia.org/wiki/Descriptive_notation

⁴https://en.wikipedia.org/wiki/ICCF_numeric_notation

different abbreviations depending on language.

Figure 3.1: Empty chessboard.

For example, **g5** refers to the following square:

Figure 3.2: Example: square **g5** highlighted and arrows pointing to it.

It is important to know that when placing a chessboard in the correct orientation, there should always be a **white square in the bottom-right corner** or a **black square in the bottom-left corner**.

3.2.2. Chess pieces

There are 6 types of chess pieces: king, queen, rook, bishop, knight and pawn, and each side has 16 pieces:

Piece	White Pieces	Black Pieces	Number of Pieces
King			1
Queen			1
Rook	 	 	2
Bishop	 	 	2
Knight	 	 	2
Pawn	       	       	8

Table 3.1: Number of chess pieces by type and color.

The starting position of the chess pieces on a chessboard is the following:

Figure 3.3: Starting position.

Notice that the queen and king are placed in the center columns. The queen is placed on a square of its color, while the king is placed on the remaining central column. The rest of the pieces are positioned symmetrically, as shown in Figure 3.3.

This means that the chessboard is divided into two sides relative to the positions of the king and queen at the start of the game:

Figure 3.4: King's side (blue) and Queen's side (red).

3.2.3. Movement of the pieces

3.2.3.1. Pawn

The pawn can move one square forward, but it can only capture pieces one square diagonally. On its first move, the pawn has the option to move two squares forward. If a pawn reaches the last row of the opponent's side, it can be promoted⁵ to any other piece (except for a king).

Figure 3.5: Pawn's movement.

Figure 3.6: Pawn attack.

⁵[https://en.wikipedia.org/wiki/Promotion_\(chess\)](https://en.wikipedia.org/wiki/Promotion_(chess))

Figure 3.7: Promotion.

Figure 3.8: Pawn promotes to queen.

There is a specific capture movement which is **en passant**⁶. This move allows a pawn that has moved two squares forward from its starting position to be captured by an opponent's pawn as if it had only moved one square. The capturing pawn must be on an adjacent file and can only capture the en passant pawn immediately after it moves.

Figure 3.9: En passant
(1).Figure 3.10: En passant
(2).Figure 3.11: En passant
(3).

3.2.3.2. Rook

The rook can move any number of squares horizontally or vertically. It can also capture pieces in the same way.

⁶https://en.wikipedia.org/wiki/En_passant

Figure 3.12: Rook's movement.

3.2.3.3. Knight

The knight moves in an L-shape: two squares in one direction and then one square perpendicular to that direction. The knight can jump over other pieces, making it a unique piece in terms of movement. It can also capture pieces in the same way.

Figure 3.13: Knight's movement.

3.2.3.4. Bishop

The bishop can move any number of squares diagonally. It can also capture pieces in the same way. Considering that each side has two bishops, one bishop moves on light squares and the other on dark squares.

Figure 3.14: Bishop's movement.

3.2.3.5. King

The king can move one square in any direction: horizontally, vertically, or diagonally. However, the king cannot move to a square that is under attack by an opponent's piece. The king can also capture pieces in the same way. The king is a crucial piece in chess, as the game ends when one player checkmates the opponent's king.

Figure 3.15: King's movement.

Figure 3.16: White King's movement in a game.

In Figure 3.16, the white king cannot move to **e4** because the black king is attacking that square. When two kings are positioned close to each other, neither can move to a square adjacent to the other.

Additionally, the king can perform a special move called **castling**, which involves

moving the king two squares towards a rook and moving the rook to the square next to the king. Castling has specific conditions which are:

- Neither the king nor the rook involved in castling must have moved previously.
- There must be no pieces between the king and the rook.
- The king cannot be in check, move through a square under attack, or end up in check.

Figure 3.17: Castling

In this case, the white king can castle on either the king's side or the queen's side as long as the rooks have not been moved from their starting position, but the black king cannot castle because there is a bishop on **f8** interfering with the movement and the rook on the queen's side has been moved to **b8**.

3.2.3.6. Queen

The queen can move any number of squares in any direction: horizontally, vertically, or diagonally. It can also capture pieces in the same way.

Figure 3.18: Queen's movement.

3.2.4. Rules

Each player aims to checkmate the opponent's king, which means that the king is under attack and cannot escape.

In every game, **white starts first** and the possible results of each game can be win for white, win for black or draw⁷. A tie could be caused by different conditions:

1. Stalemate: the player whose turn it is to move has no legal moves, and their king is not in check.
2. Insufficient material: neither player has enough pieces to checkmate. Those cases are king vs king, king and bishop vs king, king and knight vs king, and king and bishop vs king and bishop with the bishops on the same color.
3. Threefold repetition: it occurs when same position happens three times during the game, with the same player to move and the same possible moves (including castling and en passant).
4. Fifty-move rule: if 50 consecutive moves are made by both players without a pawn move or a capture, the game can be declared a draw.
5. Mutual agreement: both players can agree to a draw at any point during the game.
6. Dead position: a position where no legal moves can be made, and the game cannot continue. This includes cases like king vs king, king and knight vs king, or king and bishop vs king.

⁷[https://en.wikipedia.org/wiki/Draw_\(chess\)](https://en.wikipedia.org/wiki/Draw_(chess))

Figure 3.19: Stalemate.

Figure 3.20: Insufficient material.

Figure 3.21: Dead position.

Players can also resign at any time, conceding victory to the opponent. Also, if a player runs out of time in a timed game, they lose unless the opponent does not have enough material to checkmate, in which case the game is drawn.

For more information about chess rules, refer to the Wikipedia page: https://en.wikipedia.org/wiki/Rules_of_chess.

3.2.5. Notation

Notation is important in chess to record moves and analyze games.

3.2.5.1. Algebraic notation

In addition to the **algebraic notation** of the squares in section 3.2.1, each piece is identified by an uppercase letter, which may vary across different languages:

Piece	English Notation	Spanish Notation
Pawn	<i>P</i>	<i>P</i> (peón)
Rook	<i>R</i>	<i>T</i> (torre)
Knight	<i>N</i>	<i>C</i> (caballo)
Bishop	<i>B</i>	<i>A</i> (alfil)
Queen	<i>Q</i>	<i>D</i> (dama)
King	<i>K</i>	<i>R</i> (rey)

Table 3.2: Chess piece notation in English and Spanish.

Normal moves (not captures nor promoting) It is written using the piece uppercase letter plus the coordinate of destination:

Figure 3.22: Pawn goes to a6.

In Figure 3.22, the pawn's movement is written as **Pa6** or directly as **a6**.

Captures They are written with an "x" between the piece uppercase letter and coordinate of destination/the captured piece coordinate:

Figure 3.23: Bishop captures knight.

In Figure 3.23, the white bishop capturing the black knight is written as **Bxc6**. If it were black's turn, the pawn on **a6** could capture the white bishop, and it would be written as **Pxb5** or simply **axb5**, indicating the pawn's column.

Pawn promotion It is written as the pawn's movement to the last row, followed by the piece to which it is promoted:

Figure 3.24: Pawn captures rook.

In Figure 3.24, white pawn capturing and promoting in **a8** to a queen is written as **bx a8Q** or **bx a8=Q**.

Castling Depending on whether it is on the king's side or the queen's side, it is written as **0-0** and **0-0-0**, respectively.

Check and checkmate They are written by adding a **+** sign for check or **++** for checkmate, respectively.

Figure 3.25: Black queen checkmates.

In Figure 3.25, black queen movement checkmates and it is written as **Dh4++**.

The end of game notation It indicates the result of the game. It is typically written as:

- **1-0**: White wins.
- **0-1**: Black wins.
- **1/2-1/2**: The game ends in a draw.

For more information about notation, refer to the Wikipedia page: [https://en.wikipedia.org/wiki/Algebraic_notation_\(chess\)](https://en.wikipedia.org/wiki/Algebraic_notation_(chess)).

3.2.5.2. Forsyth–Edwards Notation (FEN)

This is a notation that describes a specific position on a chessboard. It includes 6 fields separated by spaces: the piece placement, whose turn it is to move, castling availability, en passant target square, halfmove clock and fullmove number. For example, the FEN for the starting position is:

```
rnbqkbnr/pppppppp/8/8/8/8/PPPPPPPP/RNBQKBNR w KQkq - 0 1
```

Keep in mind this notation is important for the engine to understand the position of the pieces on the board.

For more information about FEN, refer to the Wikipedia page: https://en.wikipedia.org/wiki/Forsyth%E2%80%93Edwards_Notation.

3.2.5.3. Portable Game Notation (PGN)

This notation is mostly used for keeping information about the game and a header section with metadata: the name of the event, site, date of play, round, color and name of each player and result. For example, the PGN for a game could look like this:

Listing 3.1: Example of a PGN file

```
[Event "XX Gran Torneo Internacional Aficionado"]
[Site "?"]
[Date "2024.06.25"]
[Round "1"]
[White "Tejedor Barber, Lorenzo"]
[Black "Giron Herranz, Juan"]
[Result "0-1"]

1. e4 c6 2. d4 d5 3. exd5 cxd5 4. Bd3 Nc6 5. c3 Nf6 6. Bf4 Bg4
